

F5 A fluent generation that three gates passed and the fourth refused

One evaluated context. Qwen3-1.7B and Qwen3-4B-Instruct-2507, greedy, CPU. A demonstrated failure mode — not a failure rate.

What the fourth gate caught

the generation asserted

“the G1-G6 range passed”

the evidence records

↔ **G4 and G5 BLOCKED**

It rounded correctly, ended with the canonical disclaimer and invented no number — and inverted the fact the contamination control exists to communicate.

Two properties that must be stated together

- The harness calls `provider.generate()` directly, so no runtime gate runs during evaluation: the three PASS scores describe raw model output, not what a user receives.
- The inversion reproduced on two independent runs, before and after the reasoning-mode fix, on the same context.
